AdaBoost is easy to implement, and the only meta-parameter that needs tuning is the number of boosting rounds T . It is flexible with any choice of weak learner, though simple weak learners tend to have computational benefits. Boosting can identify outliers: they are simply the datapoints with higher weights.

Background Boosting has its roots in a theoretical framework for studying machine learning called the "PAC" learning model, due to Valiant [46]; see Kearns and Vazirani [32] for a good introduction to this model. Kearns and Valiant [30, 31] were the first to pose the question of whether a "weak" learning algorithm which performs just slightly better than random guessing in the PAC model can be ...
