quires an effective soil fertility program. A comprehensive soil sampling plan is essential to a quality soil fertility program. Soil test recommendations are very reliable for most soil types if a representative sample is collected. Sampling methodology and intensity are the issues that most often plague farmers and industry professionals. With the recent

Soil sampling for spatially explicit management There are two main methods for soil sampling in spatially explicit management — zone-based sampling and grid sampling. With each method, soil samples are collected from predefined areas in a field. By correlating the soil test results with the area of the Figure 3.

in soil sampling techniques is important because of soil bulk density differences, particularly in soil cores. Sampling depth depends most on the nutrient or soil factor of interest, the crop to be fertilized and, in some cases, the tillage system in place at the time of sampling (Figure 2). Intensive grid soil sampling is conducted before and after applying the treatments. The treatments compared vary between fields and include fertilizer placements (starter, deep-banding), interactions of herbicides and fertilization, variable-rate fertilization or manuring, and others.

Each sample is analyzed for water pH, Mehlich buffer lime requirement, and for phosphorus, potassium, magnesium, and calcium by the Mehlich 3 (ICP) test. The final report includes the chemical analysis of the soil along with lime and fertilizer recommendations for the crop specified. For agronomic crops, Mehlich 3 zinc, copper and sulfur are also reported.

The sampling technique used is known as grid-point sampling. A grid-point sample consists of at least 10 cores collected from a small area (10-foot radius) around a geo-referenced point. When using a grid sampling approach, Wisconsin research recommends a sampling strategy based on an unaligned systematic grid (Figure 2).

Benchmark sampling involves selecting a small (30 m by 30 m) representative site on a field (Figure 3.3.6). This site is used as a guide for fertilizing that entire field. Select probe sampling sites in a grid pattern within the benchmark area and prepare a composite sample for each soil depth.

**Chapter 3**

Soil sampling is the best way to determine the soil pH and level of residual nutrients. It is often beneficial to establish a base level of residual nutrients in the soil over time. The ability to make sound fertility decisions are enhanced when producers apply best available sampling techniques for nitrogen, phosphorus, potassium and trace elements.

**Advancing Cotton Education** **Soil Fertility**

The same general principles that apply to soil sampling for nutrient evaluation (Staben, et al., 2003) apply to soil sampling for determination of OM. A consistent soil sampling protocol is essential. ¾ Collect soil samples to consistent soil depth(s). ¾ Maintain consistency in the number of soil cores collected per composite sample.

Both grid and directed soil sampling are valid options for precision soil sampling. Grid sampling for nitrate-N is not recommended because annual fluctuations in nitrate levels would require annual grid sampling, which is not cost-effective. Instead, residual nitrate sampling (to a depth of 3 feet) should be done on a directed sampling basis.
