A superscalar processor is a CPU that implements a form of parallelism called instruction-level parallelism within a single processor. In contrast to a scalar processor that can execute at most one single instruction per clock cycle, a superscalar processor can execute more than one instruction during a clock cycle by simultaneously dispatching multiple instructions to different execution units on the processor. It therefore allows for more throughput than would otherwise be possible at a given

CPU - this allows you to have single instructions that perform multiple actions. Now you've gone from executing one instruction per 5 clock cycles to executing multiple complete instructions per 1 clock cycle. In the best case, the CPU lights up like a christmas tree - every single unit active at the same time, all the time.

Try running this silly piece of code: You will see it print 'start func1' and then 'start func2' and then after a (very) long time you will finally see the functions end. But they will indeed execute simultaneously. Because processes take a while to start up, you may even see 'start func2' before 'start func1'.
